Endocrine System

- Major control system
 - Works with the nervous system
 - Function: to maintain homeostasis
- Both use
 - specific communication methods
 - affect specific target organs
- Their methods and effects differ.

The Endocrine System

Endocrine Glands & Hormones

- Exocrine glands: ducted
 - secretions released into ducts
 - open onto an epithelial surface
- Endocrine glands: ductless
 - secrete product directly into the bloodstream
- All endocrine cells are located within highly vascularized areas
 - ensure that their products enter the bloodstream immediately.

Hypothalamic Control of the Endocrine System

- Master control center of the endocrine system
- Hypothalamus oversees most endocrine activity:
 - special cells in the hypothalamus secrete hormones that influence the secretory activity of the **anterior pituitary gland**
 - called regulatory hormones
 - releasing hormones (RH)
 - inhibiting hormones (IH)
- Hypothalamus has indirect control over these endocrine organs.

Pituitary Gland (Hypophysis)

- lies inferior to the hypothalamus.
- Small, slightly oval gland housed within the hypophyseal fossa of the sphenoid bone.
- Connected to the hypothalamus by a thin stalk, the infundibulum.
- Partitioned both structurally and functionally into an **anterior pituitary** and a **posterior pituitary**.
 - (called anterior lobes and posterior lobes)

Control of Anterior Pituitary Gland Secretions

- Anterior pituitary gland is controlled by regulatory hormones secreted by the hypothalamus

(a) Hypothalamo-hypophyseal portal system

(b) Hypothalamo-hypophyseal tract

Thyroid Gland

- Located immediately **inferior** to the **thyroid cartilage of the larynx** and anterior to the trachea.
- Distinctive **“butterfly” shape** due to its left and right lobes, which are connected at the anterior midline by a narrow isthmus.
- Both lobes of the thyroid gland are highly **vascularized**, giving it an intense reddish coloration.
- Regulation of thyroid hormone secretion depends upon a complex **thyroid gland–pituitary gland **negative**** feedback process.

Thyroid Gland

- Follicle cells:
 - Produce and secrete **thyroid hormone**
 - Precursor is stored in colloid
- Thyroid hormone
 - Increases metabolic rate
 - Important in growth and development.
- Parafollicular cells
 - Produce and secrete **calcitonin**
- Calcitonin: is a calcium lowering hormone.

(a)

1 A stimulus (e.g., low body temperature) causes the hypothalamus to secrete thyrotropin-releasing hormone (TRH), which acts on the anterior pituitary.

2 Thyrotropic cells in the anterior pituitary are stimulated to release thyroid-stimulating hormone (TSH).

5 Increased TH levels cause heat production in target cells; that increase in temperature is detected by the hypothalamus as it monitors blood temperature and inhibits the secretion of TRH by the hypothalamus. TH also blocks the interactions of TRH from the hypothalamus and anterior pituitary to prevent the formation of TSH.

4 TH stimulates target cells to increase metabolic activities, resulting in an increase in basal body temperature.

3 TSH acts on cells of the thyroid gland. Follicular cells are stimulated to release thyroid hormone (TH).

Parathyroid Glands

- Small, brownish-red glands
 - located on the **posterior** surface of the thyroid gland
- Usually **four** small nodules

(a)

Adrenal Glands (suprarenal)

- Paired, pyramid-shaped endocrine glands anchored on the superior surface of each kidney.
- Outer **adrenal cortex** and an inner central core called the **adrenal medulla**.
 - secrete different types of hormones

Adrenal Cortex

- Distinctive **yellow** color due to stored lipids in its cell.
- Synthesize more than **25 different steroid hormones**, collectively called **corticosteroids**.
- Regulates salt, sugar, and sex.

Adrenal Medulla

- Forms the inner core of each adrenal gland.
- Pronounced **red-brown color** due to its extensive **vascularization**.
- Hormones work with the sympathetic **nervous system** to prepare the body for an **emergency** or **fight-or-flight situation**.

Pancreas

- Elongated, spongy, nodular organ
 - between the duodenum and the spleen
 - posterior to the stomach.
- Both **exocrine** and **endocrine**:
- The **endocrine portion secretes insulin and glucagon.**

Pineal Gland

- Pineal gland or **pineal body**, is a small, cone-shaped structure attached to the posterior region of the epithalamus.
- Secretes **melatonin**.
 - helps regulate a **circadian rhythm (24-hour body clock)**
 - also appears to affect the synthesis of the hypothalamic regulatory hormone responsible for FSH and LH synthesis
 - role in **sexual maturation** is **not well understood**

The Pineal Gland

Thymus

- A **bilobed** structure located within the mediastinum superior to the heart and immediately posterior to the sternum.
- **Size** of the thymus **varies** between individuals.
 - it is always relatively **large** in infants and children
 - as with the pineal gland, the thymus **diminishes in size** and activity with age, especially after puberty
- Functions principally in association with the **lymphatic system** to regulate and maintain body **immunity**.
- Produces complementary hormones **thymopoietin** and **thymosins**.
 - hormones act by stimulating and promoting the differentiation, growth, and maturation of a category of lymphocytes called **T-lymphocytes** (thymus-derived lymphocytes)
